Hot Air Engine

A hot air engine is any heat engine that uses the expansion and contraction of air under the influence of a temperature change to convert thermal energy into mechanical work. These engines may be based on a number of thermodynamic cycles encompassing both open cycle devices such as those of Sir George Cayley and John Ericsson and the closed cycle engine of Robert Stirling. Hot air engines are distinct from the better known internal combustion based engine and steam engine. In a typical implement

Hot air engine - Wikipedia

The hot air (Stirling Cycle) engine is a unique style of engine cycle. Basically the engine functions by heating and cooling a captured volume of air. These engines have no intake or exhaust. At one end of the cycle the air is heated which builds pressure forcing the piston up. At the opposing end of the cycle the same volume of air is then cooled, creating a partial vacuum and uses atmospheric pressure to force the piston back down.

Hot air engines use the heating and cooling and expansion and contraction of air to generate power. The hot air engine was once very popular for light duties, largely because of what it did not have; a boiler. It was impossible to have a boiler explosion.

This is an exquisitely crafted Stirling Engine, built from brass and glass by Jos de Vink (Jos the Finch). It's a perfect demonstration of the engine's stunning efficiency: The pistons and flywheels are driven by nothing more than the heat from four tea-lights. There are plenty more of these beautiful machines on Jos's website, and [...]

A Stirling engine is a heat engine that is operated by a cyclic compression and expansion of air or other gas (the working fluid) at different temperatures, resulting in a net conversion of heat energy to mechanical work. More specifically, the Stirling engine is a closed-cycle regenerative heat engine with a permanent gaseous working fluid.

Stirling engine - Wikipedia

A Stirling engine fan integrates a Stirling engine and a fan to move air where you either don't have, or don't want to use, electricity. They are usually powered by a kerosene or alcohol flame or the heat from a hot wood stove. Summary of the Article Below The article below explains how Stirling fans work, including an animation.

The hot-vapor engine did all this running unheard of high temperatures at an extremely lean air/fuel ratio, in seeming violation of accepted internal-combustion-engine physics. Normally, different...

The Stirling engine is a closed cycle heat engine. It is typically completely sealed from the outside environment and works on the expansion and compression of the gas (typically air) that's enclosed in the sealed engine. Fuel does not move through the engine like in a conventional internal combustion engine.

It is so simple like every other hot air engine. Start to heat up the air in the engine and it will expands. This expansion can move out the piston from the cylinder. And when the air is cooled then the piston will move back.

New generation of hot air engines: Manson engine

In his patent Stirling describes the use of the regenerator (economiser) for an air engine but also for other applications like furnaces to the saving of fuel in breweries, distilleries, dye works and other manufactures. Here we reproduce only the application to the hot air engine.

This is a very good demonstration of the Stirling engine cycle. You can clearly see the expansion and contraction of the gas while inflating and deflating the balloon. Near the end of the video he runs the Stirling hot air engine. He also talks about efficiency and heat lost. Quote from the Principles of a Stirling Hot Air Engine Description:
